Membrane Protein Purification and Characterization of Protein-detergent Complexes-Kelley Kearns 2012 Representing one third of the proteins encoded by an organism's genome and 60% of all human drug
targets, membrane proteins are ubiquitous and hold the key to structure-based design of therapeutics. Despite the great interest surrounding membrane proteins, they are grossly underrepresented in the Protein Data Bank due in large part to the inherent difficulties of working with macromolecules with extensive hydrophobic surfaces. Detergents are typically used to isolate and characterize membrane proteins, but maintenance of the native protein structure in detergent solutions presents a major challenge. Another bottleneck to structural determination of membrane proteins is the production of high-quality, three-dimensional crystals for x-ray diffraction, which remains a difficult and largely empirical task due to the complexity of the crystallizing solutions and the vastness of the multi-dimensional parameter space. Crystallization of membrane proteins is favored near the phase boundaries of surfactant solutions, and we find here that more specific characteristics of the surfactant and polymer phase behavior and resulting surfactant microstructure may play a major role in facilitating the interactions required for crystallization. The objective of this work is to understand the stabilizing role of detergents, while identifying specific detergent properties that are predictive of the effectiveness towards stabilization and crystallization of membrane proteins. The stability of E. coli diacylglycerol kinase was studied in detergent mixtures in order to gain an understanding of the cause of protein instability in detergent solutions. The adapted stability assay revealed that changes in the mixed micelle composition correlate directly with the thermostability of the protein. Excess concentrations of small amphiphiles relative to the solubilizing detergent can significantly impact micelle composition and structure and adversely affect protein stability. Cryogenic-transmission electron microscopy images of protein-free solutions near several reported crystallization conditions reveal microdispersions consisting of a dense, surfactant-rich phase interspersed within the bulk solvent phase. The microstructure of the surfactant-rich phase varies from elongated micelles arranged in a
hexagonal lattice to a randomly branched micellar network. The existence of such microstructures and the intermicellar ordering, which are both reminiscent of the mesophases that are used in the crystallization of membrane proteins in meso, suggest that a similar mechanism may be responsible for 3D crystallization in detergents.

Purification and Characterization of Surfactant Protein-A Binding Proteins - David Michelis 1995
Knowledge of the three-dimensional structure of a protein is absolutely required for the complete understanding of its function. The spatial orientation of amino acids in the active site of an enzyme demonstrates how substrate specificity is defined, and assists the medicinal chemist in the design of specific, tight-binding inhibitors. The shape and contour of a protein surface hints at its interaction with other proteins and with its environment. Structural analysis of multiprotein complexes helps to define the role and interaction of each individual component, and can predict the consequences of protein mutation or conditions that promote dissociation and rearrangement of the complex. Determining the three-dimensional structure of a protein requires milligram quantities of pure material. Such quantities are required to refine crystallization conditions for X-ray analysis, or to overcome the sensitivity limitations of NMR spectroscopy. Historically, structural determination of proteins was limited to those expressed naturally in large amounts, or derived from a tissue or cell source inexpensive enough to warrant the use of large quantities of cells. However, with the advent of the techniques of modern gene expression, many proteins that are constitutively expressed in minute amounts can become accessible to large-scale purification and structural analysis.

The Expression, Purification and Characterization of Human Kinesin-13 Protein Kif2b, with Preliminary Structural Analysis-Qian Li 2015 In humans, the kinesin-related protein Kif2b, a potent regulator of microtubule dynamics, plays an important role in high fidelity chromosome segregation during mitotic progression. As with some other members of the kinesin 13 subfamily, Kif2b is unusual in that its activity is regulated by phosphorylation, and phosphorylation at threonine 125 and serine...
204 can regulate the activity and function of Kif2b in microtubule dynamics. Due to the lack of detailed structural information, the molecular basis for regulation by phosphorylation, as well as the mechanism of microtubule depolymerization catalyzed by Kif2b, is unknown. In order to investigate these activities, the primary goal of this project was to determine the high-resolution crystal structure of the Kif2b catalytic domain, as well as the phosphomimetic mutants Kif2b\textsuperscript{T125D}, Kif2b\textsuperscript{S204D} and Kif2b\textsuperscript{T125D, S204D}. As bacterial expression and protein purification protocols for of Kif2b have not been described previously, we successfully developed a purification of the Kif2b motor domain involving a three-step protocol including ion-exchange chromatography, affinity chromatography, and size-exclusion chromatography. Characterization using circular dichroism (CD) spectroscopy and differential scanning calorimetry (DSC) illustrated a well-folded Kif2b motor domain with denaturation temperatures between 31 and 34 °C and a robust ATPase activity was confirmed using EnzChek phosphate assay. Although preliminary crystals were obtained for the wild-type construct, diffraction was not yet observed. Finally, to identify the structural consequences of phosphorylation, the phosphomimetic mutants Kif2b\textsuperscript{T125D}, Kif2b\textsuperscript{S204D} and Kif2b\textsuperscript{T125D, S204D} were generated and purified following a similar procedure to the wild-type motor domain.
